

Important: Avoid @Effect

In this section, we create NgRx effects via the `@Effect` decorator.

Whilst this works in older versions (and might therefore still be encountered in many Angular projects), you should now create effects via the `createEffect()` function instead.

Instead of this code:

1. `@Effect`
2. `authLogin = this.actions$.pipe(...)`

(as I'll write it in the next lecture)

You should write this code:

1. `authLogin = createEffect(() => this.actions$.pipe(...));`

`createEffect` must be imported from `@ngrx/effects`

1. `import { createEffect } from '@ngrx/effect';`

Also see: <https://ngrx.io/guide/migration/v15#removal-of-effect>
